Abstract: This report was prepared in accordance with the Department's responsibility for projecting economic and demographic trends for the State and its political subdivisions. The report provides industry sector employment projections to 1990 by five year intervals and age, race and sex specific population projections to 1990. Total population is also projected to the year 2000 for those organizations requiring longer-term projections.

The projections of employment and population provided in this report are part of a system of integrated projections of labor force, household formation, personal income and detailed occupational attributes of the labor force. Future reports in the series will present information developed by this system. An analysis of the information contained in the present report is also forthcoming.

The Honorable Marvin Mandel
Governor of Maryland
State House
Annapolis, Maryland 21404

Dear Governor Mandel:

I am pleased to transmit herewith the Department's recently-completed report, "Maryland Projection Series - Population and Employment, 1975-1990."

Prepared by our Planning Research Program Division, the report embraces population and employment projections for the State and its political subdivisions by five year intervals from 1975 to 1990. The population projections are broken down by age, sex and race and the employment projections by detailed industrial sectors.

I believe that the Department's projection series are important analytical tools for planning carried out by State and local public agencies. It is anticipated that they will have wide-ranging applicability also for research and analysis undertaken within the private sector.

Accordingly, copies of the report are being distributed to interested agencies and individuals throughout the State.

Sincerely,

Vladimir Wahbe

Vladimir Wahbe

Enclosure

V

I. INTRODUCTION

This report was prepared in accordance with the Department's responsibility as mandated by law for projecting economic and demographic trends for the State and its political subdivisions (Article 88C, Annotated Code of Maryland). Derived through the application of a linked employment-population projection model developed by the Division of Planning Research Programs, it is anticipated that the information embraced by the report will be useful to both public and private organizations and vital for purposes of both functional and comprehensive planning. The model provides industry sector employment projections to 1990 by five year intervals and age, race and sex specific population projections to 1990. Total population is also projected to the year 2000 for those organizations requiring longer-term projections.

In order to utilize the model properly, considerable attention was given to the task of providing a time series of estimated detailed industry sector employment for the period 1962-1973 for each subdivision of the State. The construction of this series made use of unpublished sources of employment data and utilized estimation procedures which serve to provide comprehensive coverage and update capability.

The projections of employment and population provided in this report are part of a system of integrated projections of labor force, household formation, personal income and detailed occupational attributes of the labor force. Future reports in the series will present information developed by this system. An analysis of the information contained in the present report is also forthcoming.

II. THE LINKED EMPLOYMENT-POPULATION PROJECTION MODEL

The selection of procedures for projecting economic and demographic variables for subdivisions within Maryland represents an attempt to account for the relationship of employment to population and to provide sufficiently detailed information concerning these variables. Operationally, the linked employment-population projection model assumes that an examination of the interaction between the demand for and supply of labor will provide the best estimate of population change. Accordingly, determination of the migration component, is a function of labor force demand and supply. The population projections, therefore are not dependent upon estimates of net migration based solely on the previous decade, or upon the use of a fixed migration rate.

The linked employment-population projection model is a computer based computational technique consisting of two linked submodels: a demographic submodel and an employment submodel. Therefore the model has the capability to trace the interdependence of demographic and economic factors in a consistent manner and provide detailed information concerning the age, race, and sex specific characteristics of an area's population and labor force and employment by industry.

The analytical approach underlying the model requires an understanding of prospective socioeconomic trends for the nation and in addition, a detailed understanding of unique characteristics of local areas of the State. The projection procedures utilized represent an adaptation of export-base theory. For each local area of the State, activity sectors engaged in the production of goods and services to be sold outside the local area is projected as a first approximation. Employment in these activity sectors generate income which is in turn spent on local goods and services that generate additional employment and income. Resultant employment demand balances are compared to natural increases in the population and labor force in order to determine whether or not an excess of job opportunities are likely to induce migration into the area to fill resultant vacancies, or alternatively to induce outmigration from the area given a shortage of job opportunities.

In determining the magnitude of the migration component, evaluation in the context of strategic attributes of area populations such as fertility rates, labor force participation rates, age, sex and race specific characteristics of migration flows, were explicitly delineated in the model structure and trended over the projection period.

The resultant projections can be considered as a best estimate of the levels of population and employment that will obtain in the absence of area policy changes of an unusual nature. Therefore they do not imply either a policy goal or a constraint upon activity sectors within any given local area. The application of these projections should not serve to constraint the positing of alternative rates of growth which may be achievable given different levels of resource development. Therefore, the projections of population and employment provide a framework for policy evaluation.

In the following sections of this study, assumptions and methodology are specified. Updating of the projections are anticipated to be carried out on an annual basis. This is necessary to provide a mechanism in which area alternative development strategies can be assessed and incorporated in terms of overall impact upon employment and population.

A. THE POPULATION PROJECTION SUBMODEL: ASSUMPTIONS AND DATA BASE

Base Population Data

The 1970 political subdivision[1] population data, detailed by age, race and sex, were originally taken from the 1970 Census of Population and Housing First Count Summary Tapes. In a few cases, the figures differ slightly from the First Count data to reflect some minor corrections made by the Bureau of the Census in allocating persons to the correct political subdivision. Such corrections are negligible.

Mortality Assumptions and Data

In most forecast models, rather than calculating the number of persons that die during a five year period, a computation is made of the number of persons that survive from the beginning to the end of the period. Thus, the opposite of the death rate, the survival rate, is incorporated in population forecasts. In this study, 5-year age-specific survival rates are calculated from available life tables[2] and used in the model.[3]

1 Political subdivisions referred to are the 23 counties and Baltimore City.

2 The life table is a life history of a hypothetical group, or cohort, of people, as it is diminished gradually by deaths. The record begins at the birth of each member and continues until all have died.

3 Survival rates were taken from David L. Kruegel and Jennifer M. Peck, "Maryland Abridged Life Tables, by Color and Sex: 1969-71," Maryland State Medical Journal. January, 1974.

The appropriate calculation of the probability of survival during a five-year period, ${}_5S_x^5$ is,

$$ {}_5S_x^5 = \frac{{}_5L_{x+5}}{{}_5L_x} $$

where

${}_5L_x$ = The number of persons-years lived during a five year time interval (from the life table).

${}_5L_{x+5}$ = The number of person-years lived during the next five year time interval (from the life table).

A special computation is needed for the terminal age group. Since ${}_nT_x$ represents the cohort population in year x and all subsequent years, values of T_x rather than ${}_nL_x$ are used. The survival rate for a five year period for all persons 75 years of age and over at the beginning of the period can be computed by dividing T_{80} by T_{75}. The survivors thus calculated, which now become those aged 80 and over, must be added to the survived population 75-79 to become the population now 75 and over.

In addition, births during each five year interval must be survived. The survival rate for babies from birth to the 1-5 age interval is computed by the following formula:

$$ {}_5S_0 = \frac{{}_4L_0}{4l_0} $$

where

$_4L_x$ = Number of person-years lived during the 1-5 year time interval (from the life table).

l_0 = Four cohorts of 100,000 each that are subject to death.

Fertility Assumptions and Data

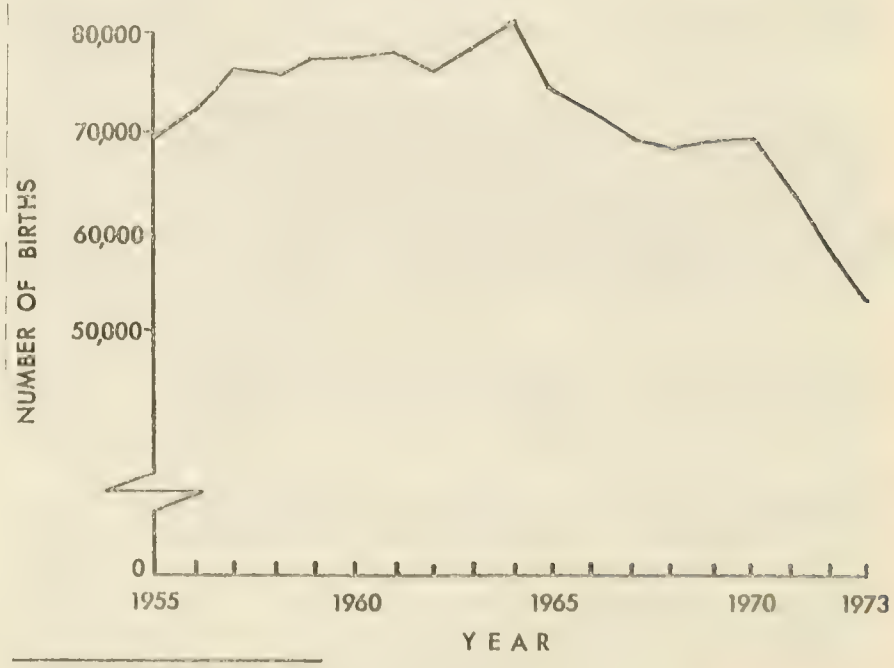
The number of births in Maryland rose steadily until 1964 when it peaked at 79,003 (Figure I). Since 1964, the number of births has been declining annually with the exception of 1969 and 1970, when a slight upward deviation from the general trend was observed.

In recent years the decline in births has been extremely dramatic. From 1970 to 1971 a decrease of 3,937 births was recorded, from 1971 to 1972, 7,089 births, and from 1972 to 1973, 5,015 births. (The number of births by county from 1942 to 1973 are found in Appendix A.) These figures reflect changes in crude birth rates, which peaked in 1957 at 26.3 births per thousand population and declined to 13.1 births per thousand population in 1973.

The general fertility rate (births per thousand females aged 15-44) has also experienced a downward trend for both white and nonwhite sectors of the population. In 1960 the general fertility rate for whites was 108, compared to 138 for nonwhites. By 1970, the white general fertility rate had dropped to 77, a decline of 29 percent over the period, while the nonwhite general fertility rate fell to 100, a decline of 28 percent. (General fertility rates by white-nonwhite groups for each county for 1960 and 1970 are found in Appendix B.)

The Bureau of the Census has made four assumptions regarding total fertility, Series C assumes that each 1,000 women will have 2,800 children or 2.8 children per woman. This is the highest of the total fertility rates now used. Series D assumes 2.5 births per woman, Series E, 2.1 births and Series F assumes a total fertility rate of 1.8 births per woman.[4] In view of observed birth and fertility rate trends in Maryland during recent years, the national Series F fertility trend was followed in the forecast model until 1980, then the national Series E trend was used from 1980 to 1990.

FIGURE I
TOTAL BIRTHS IN MARYLAND
1955 - 1973



4 U.S. Bureau of the Census, "Population Estimates and Projections" Current Population Reports, Series P-25, No. 493, December 1972.

Age-specific fertility rates for 1972 were computed for each county in Maryland. Births by age and race of mother for each 5-year age group for ages 15-44 were divided by the number of females of corresponding age and race and then multiplied by 1000 to arrive at the number of births per 1000 females in each 5-year age group. Age-specific rates for each subdivision were projected for five year periods to the year 1990 by applying to them expected percent changes in the age-specific rates for the United States according to the Series F and E assumptions (Figure II). The number of births for each political subdivision was derived in this manner for each five year period of projection. This method takes into consideration the individual patterns of fertility for each subdivision.

Accordingly, the calculation of births in a given subdivision during a specific five year time period is as follows:

$$B = \left[\sum_{x=15}^{44} {}_5{}^{i}x \cdot {}_5P_x^{f} \right] \cdot 5$$

where

B = The total number of births.

${}_5{}^{i}x$ = The fertility rate of a 5-year age group.

${}_5P_x^{f}$ = The female population in a 5-year age group.

In the above calculation, the age-race specific fertility rate for females 15 to 19 is multiplied by the number of females within the same age bracket to determine the number of births resulting from the 15 to 19 year old population. The same calculation is performed for each succeeding 5-year age group up to and including females 40 to 44. The births from each age interval thus computed are totaled to yield the number of births during one year. Finally, this figure is multiplied by 5 to compute the total number of births during the five year time period.

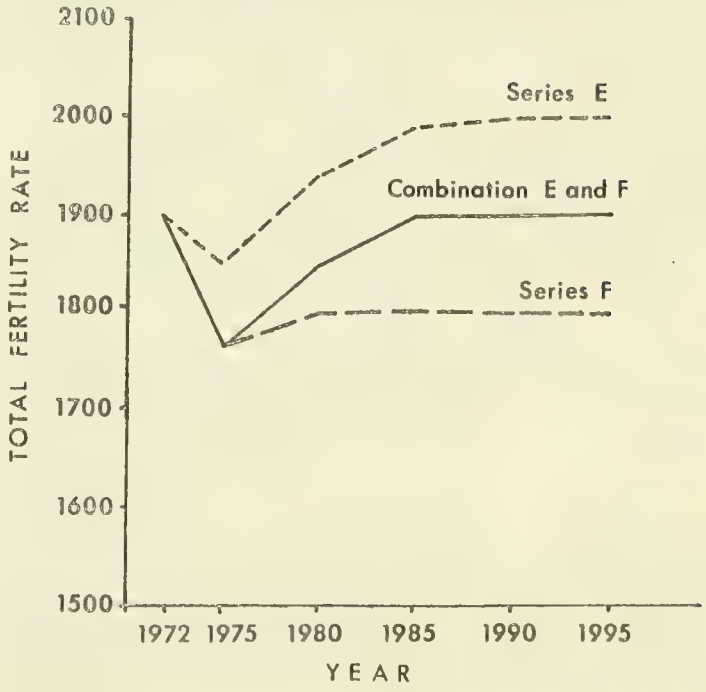
PROJECTED TOTAL FERTILITY RATE
(Total Number Of Children That 1000 Women Will Bear In Their Lifetime)



Historical Migration Data

In order to have a first approximation of the age, race and sex distribution of migrants, a five-year average migration pattern for each subdivision was calculated from data collected for the 1960-1970 period.[5] These data form an integral part of the procedure to allocate a subdivision's migrants during the first projection period along with the historical distribution of civilian population. At the end of each projection period when a new migrant matrix has been calculated, it becomes the historical migration distribution for the succeeding time period.

Special Populations

It is frequently observed that identifiable groups within the population deviate significantly from the character of the population as a whole. One such group found in Maryland is the military population and their dependents.

The military population is not functionally related to overall population growth, since the federal government regulates its locational distribution and size according to national and international considerations. The age distribution of the military is skewed toward a young male population.

Since little information is available about future changes in Maryland's military population, the decision was made to hold the military population constant over the forecast period. The number of persons in the armed forces residing in each political subdivision in Maryland in 1970 by race and sex is available from the 1970 Census of Population and Housing Fourth Count Summary Tapes (Appendix C). Allocation of the county-level military population to specific 5-year age groups is based on the State-level age distribution of the military forces.

Labor Force Participation Rates

In order to relate the size of the labor force[6] to population size at some future point in time, it was necessary to forecast the labor force participation rate. The civilian labor force participation rate is defined as the proportion of persons in the civilian labor force to the civilian population in the same age range.

A base set of civilian labor force participation rates were calculated for each subdivision by age, race and sex from data retrieved from the 1970 Census of Population and Housing Fourth Count Summary Tapes. The 1970 subdivision rates by age, race and sex were projected by five-year intervals to 1990, by using the national labor force participation rate forecasts as a base.[7] For consistency, the national rates reflecting the impact of Series E fertility rates on the availability of females for employment are used. Unemployment rates were projected using a similar procedure.

---

5 Migration distribution taken from Gladys K. Bowles, United States Department of Agriculture, Poverty-Migration Projects (preliminary figures), University of Georgia, Athens, Georgia.

6 The labor force is comprised of all persons ages 16 and over who are employed or unemployed but actively looking for employment.

7 See: Denis F. Johnston, "The U.S. Labor Force: Projections to 1990," Monthly Labor Review, July 1973, pp. 3-13.

Calculation of Commutation Ratios

Since the employment projections used in the model represent employment at place of work, it was necessary to adjust employment to the place of worker's residence. The employment projections by place of residence would thus be consistent with county-level demographic and labor force data from the 1970 Census. The adjustment was made by calculating the 1970 ratio of employment by place of work to the number of workers residing in the political subdivision and subsequently multiplying the ratio by each five-year projection of employment in the subdivision:

$$\text{Commutation ratio} = \frac{\text{1970 total employment in county}}{\text{1970 number of workers residing in county}}$$

It should be noted that the above calculation performs a twofold function: first, an adjustment is made for commuters; secondly, an adjustment is made for multiple jobholders, since the ratio compares employment expressed as jobs to the number of people who are working. Commutation ratios are modified over time in accordance with the 1960 to 1970 trend.

B. THE POPULATION PROJECTION SUBMODEL: METHODOLOGY

The purpose of the submodel is to project the population of each Maryland political subdivision by age, race and sex for five-year periods using 1970 as the base year and 1990 as the terminal year. The submodel includes three major operations in projecting the change in population in each five year interval: surviving the population existing in a subdivision at a given time period, comparing the labor force supply to the labor force demand and adjusting the population as a result of migration.

In the most general terms, the submodel attempts to generate projections of the three components of population change-births, deaths and migration. Of these three components the mortality calculation is the simplest, since survival rates tend to show relatively little change over time. Projected births, by comparison, are more subject to short-run changes resulting from postponement of family formation, economic conditions, and attitudes toward birth control and family size. The projection of migration requires greater attention. The submodel assumes that the decision to migrate is closely related to employment opportunities, and while the composition of the existing population plays some role in generating migration, projected employment is the major force in determining migration flows. The following discussion presents a detailed description of the three procedures used to project the population of Maryland's counties to 1990.

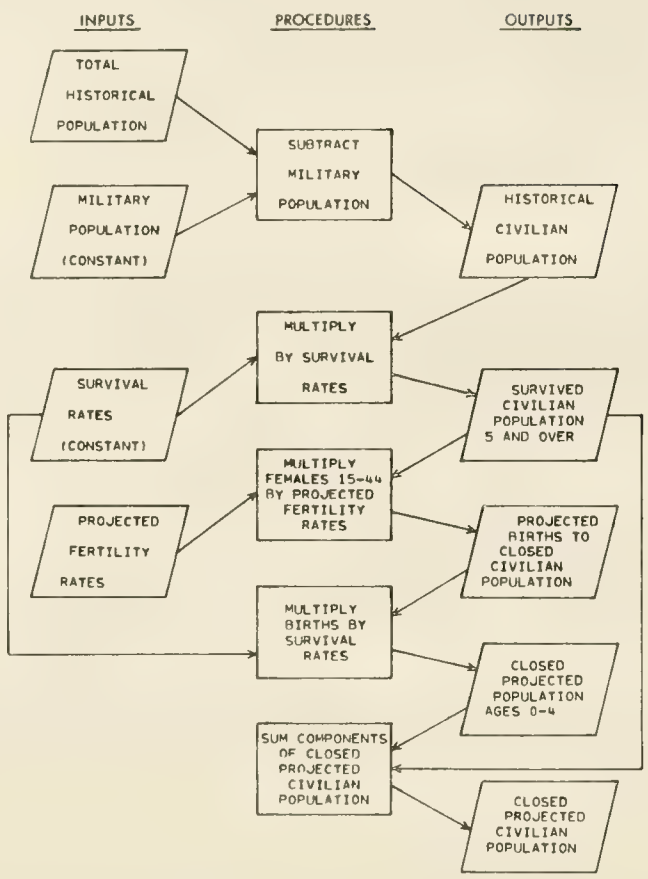
The Cohort Survival Procedure

The cohort-survival procedure considers changes in population resulting only from births and deaths, and thus deals with a closed population, i.e., one in which migration has not occurred (Figure III).

The first step in the procedure for each five year time period for each subdivision is to subtract the military population from the total population to create a historical civilian population, distributed by age, race and sex. The term historical refers to a population existing at the beginning of a projection interval.

The historical civilian population is then multiplied by the age, race and sex specific survival rates, (i.e., the probability of living from the beginning to the end of the age interval) to factor out deaths in the existing population during the time period. The result is a projected closed civilian population five

FIGURE III
PROCEDURE I. COHORT SURVIVAL



years old and over - one that has been "aged" five years.

The number of births occurring to the projected closed civilian population is calculated by multiplying the survived female population, ages 15 to 44 (in five-year age groups) by age and race-specific central fertility rates. This product is then multiplied by 5 to represent the 5-year time interval. The projected age and race-specific fertility rates vary over time and by subdivision. The projected births are then survived and thus become the 0 to 4 age group of the closed projected civilian population. At this point, only births and deaths to the closed population have been considered as components of population change. The following discussion describes the manner in which migration is generated during a time period.

Labor Force Supply and Demand Procedure

The process of migration is perceived as one in which opportunities, localized to the subdivision are responded to by the movement of population. The greatest source of opportunity stems from growth of the local economy as reflected by increased employment. The labor force demand is selected for this reason as the major impetus of migration.

Two steps are required to derive the projected labor force demand (Figure IV). First, projected employment by place of work is adjusted to employment by place of residence by application of the subdivision commuter ratio. Second, the projected employment by place of residence is divided by the complement of the projected unemployment rate, resulting in the projected labor force demand.

The projected labor force supply is calculated by multiplying the closed projected population by the age,

PROJECTED TOTAL NET MIGRATION

race and sex-specific labor force participation rates previously projected for each time period and each subdivision.

The projected migrant labor force is determined by subtracting the closed projected labor supply from the projected labor force demand. If the difference between demand and supply is positive it is assumed that a surplus of employment opportunities exist, and net in-migration will be stimulated. Alternatively, if the difference between projected labor force demand and supply is negative, i.e., the labor force supply is greater than demand, then outmigration will result.

In order to calculate the projected total net migration for a time interval, the projected migrant labor force is multiplied by a ratio of the projected closed population to the projected labor force supply. The ratio in effect represents a type of dependency ratio by which the migrant labor force can be inflated to a migrant population, inclusive of dependents.

Migration Distribution Procedure

It is necessary to allocate projected total net migration by age, race and sex in order to project births to migrant females and to bring together the various components of the population projected to the net time interval (Figure V).

Accordingly, projected total net migration is allocated by age, race and sex on the basis of the historical age, race and sex distribution of net migrants, weighted by the relative size and demographic composition of the historical civilian population. By using the historical migration pattern, both in-migration and outmigration can occur in different age, race and sex groups, but the net figure will be the projected total net migration.

PROJECTED OPEN CIVILIAN POPULATION
MILITARY POPULATION (CONSTANT)
ADD MILITARY POPULATION TO PROJECTED OPEN POPULATION
PROJECTED OPEN TOTAL POPULATION

After migrants have been distributed, the births to migrant females ages 15-44 are calculated by applying the appropriate projected fertility rates. The projected births to female migrants are survived to form a group of children ages 0 to 4 born to migrant females.

The projected open civilian population is then tabulated by adding together the projected closed population, projected net migrants by age, race and sex and projected children born to female migrants. The projected open total population is reached by adding the military population to the projected closed civilian population.

The entire model is reiterated for each successive time interval for each subdivision, using the designated projected rates for fertility, unemployment and labor force participation and projected employment levels.

C. THE EMPLOYMENT PROJECTION SUBMODEL

Introduction

The employment submodel selected for use in projecting future employment trends in subdivisions of the State utilizes an economic base approach. In this export base model, the growth process within an area's economy is visualized as an iteration between activity sectors considered as basic and other activity sectors considered as dependent or non-basic. Basic activity sectors are classified as those primarily producing for export and non-basic activity sectors are those that produce primarily for local demand. In the employment submodel, basic activity sectors include agriculture, mining, manufacturing and federal government. Federal government is classified as basic because its employment levels are largely influenced by federal expenditures

over which local areas have no control. Non-basic activity sectors include the residual, i.e., construction, transportation, communication and public utilities, wholesale and retail trade, finance, insurance and real estate services, and State and local government.

The export base model analyzes trends in both inter and intraindustry relationships and projects those relationships within the context of a national framework. Employment in basic activity sectors is related to an area's ability to compete with other areas for a portion of the total market share. Changes in a basic activity sector's share of employment can be perceived as a response to changes in total market factors external to the area. The employment submodel assumes therefore that local area basic activity sector employment is a function of total market demand for output, and changes in these shares over time reflect gains or losses in the local area's competitive position vis-a-vis other areas.

Basic Employment

Employment in non-basic or localized activity sectors is related primarily to the demand by local area households and businesses for goods and services. However, not all of this demand is local. Output in excess of local demand is exported and output below local demand is imported. It is accordingly necessary to divide non-basic employment into two separately determined components, export and residentiary. The residentiary component of a non-basic activity sector represents that part of sector employment which services local area households and businesses, and is functionally related to the growth generating activity sectors, i.e., basic and/or export components of non-basic activity sectors. To deal with the functional relationships in the model a step-down approach was utilized. Area employment in a basic activity sector is related to the historical and projected values of a corresponding activity sector within a broader area. For the State, employment in national activity sectors, and for subdivisions, employment in State activity sectors were utilized as the corresponding exogeneous values. More specifically, local area or county employment in each basic activity sector was expressed as a share of the activities in an analytical region, i.e., nation and State, and extrapolated for future years using the least square method. The projected share was in turn multiplied by the projected employment in the analytical region to yield the absolute employment in the corresponding activity sector in the local area.[1]

Localized Employment

The export component of non-basic employment in a local area was estimated for the historical period by use of an employment to population ratio in the analytical region. The export component in a local area was projected as follows: local area shares of analytical region employment were trended to determine future values. The resultant projected local area share was multiplied by the projected analytical region's employment to obtain projected local area employment. Employment in all basic industries and all export components of non-basic industries added together yielded the export base or "growth generating employment" in the model.

Residentiary employment was projected by applying projected growth generating employment to projected multipliers. The interindustry relationship between residentiary and growth generating employment which is often called an "impact coefficient" or "export base multiplier" was estimated for the historical period and

1 National employment for each activity sector was obtained from Regional Economic Projections 1960-65, National Planning Association Report Number 73-R-1, December 1973, and unpublished values for 1990.

projected into the future. Then projected total employment in each non-basic activity sector was obtained by adding together the projected export and residentiary components.

Evaluation and Adjustments

The foregoing has described the structure of the model. There are two critical variables, i.e., the local area's share of the analytical region's growth generating employment and the export base multiplier for localized industries. The system of equations descriptive of the projection procedure utilized are listed in the following section. The initial set of values obtained were evaluated in light of other economic attributes such as industrial structure, industrial productivity, specialization and self-sufficiency. Where necessary, critical parameters were modified to result in a more reasonable set of projections for relevant activity sectors.

Projection Equations

1) The historical series of State employment in each basic industry was expressed as a share of corresponding national employment.

$$Y_{ist} = B_{ist}/B_{iut}$$

where:

Y = State share of total national employment.
B = employment in a basic industry.
i = subscript denoting basic industry i.
s = subscript denoting the State.
t = subscript denoting year t.
u = subscript denoting national total.

A least squares trend line was then fitted to these State shares over time, and an extrapolation was made for the projection period.

$$Y_{ist} = a + bT$$

where:

a = the statistically derived constant.
b = the statistically derived coefficient for estimating Y over time.
T = year T.

A projection of State employment was then obtained by multiplying the projected State share times the projected national total.

$$B_{ist'} = Y_{ist'} B_{iut'}$$

where:

t' = some future year.

County projections were obtained in the same manner based on county percentages of the statewide total.

$$Y_{ict} = B_{ict}/B_{ist}$$

$$Y_{ict} = \alpha + \beta T$$

$$B_{ict'} = Y_{ict'} B_{ist'}$$

where c denotes county and α and β are the derived parameters in the county least squares regression equation.

2) Total employment in each non-basic industry was divided into its export and residentiary components using the analytical area's ratio of total employment to total population.

$$\left(\frac{N_{jst}}{P_{st}} - \frac{N_{jut}}{P_{ut}} \right) P_{st} = E_{jst}$$

$$\left(\frac{N_{jct}}{P_{ct}} - \frac{N_{jst}}{P_{st}} \right) P_{ct} = E_{jct}$$

where:

N = employment in a non-basic industry.
j = subscript denoting non-basic industry.
E = export component of the non-basic industry.

3) Following the procedure used for basic industries, the export component for each non-basic industry for the State and for each county was projected.

$$H_{jst} = E_{jst}/N_{jut}$$

$$H_{jst} = a + bT$$

$$E_{jst'} = H_{jst'} N_{jut'}$$

and

$$H_{jct} = E_{jct}/N_{jst}$$

$$H_{jct} = \alpha + \beta T$$

$$E_{jct'} = H_{jct'} N_{jst'}$$

where H is the export component of the area's non-basic industry employment, j is a subscript denoting the non-basic industry, and all other terms are defined as above.

4) Employment in all basic industries and the export components of all non-basic industries were then summed to obtain State and county totals for historical and projected years.

$$G_{st} = \sum B_{ist} + \sum E_{jst}$$

and

$$G_{ct} = \sum B_{ict} + \sum E_{jct}$$

where G is total growth-generating employment.

5) The residentiary component for each non-basic industry was estimated as the difference between the industry total and the export component.

$$R_{jst} = N_{jst} - E_{jst}$$

and

$$R_{jct} = N_{jct} - E_{jct}$$

where R is the residentiary component.

6) The residentiary component of non-basic industries in the State and each county were then divided by their corresponding growth components. These ratios (i.e., multipliers) were then projected using the least squares technique.

$$I_{jst} = R_{jst}/G_{st}$$

$$I_{jst} = a + bT$$

and

$$I_{jct} = R_{jct}/G_{ct}$$

$$I_{jct} = \alpha + \beta T$$

where I is the export base multiplier.

7) Projections of residentiary components of non-basic industries were obtained by multiplying the projected multipliers times the projected growth components, for the State and counties respectively.

$$R_{jst'} = I_{jst'} \, G_{st'}$$

$$R_{jct'} = I_{jct'} \, G_{ct'}$$

8) Finally, projections of total employment in non-basic industries were obtained by adding projected export components and projected residentiary components, for the State and for each county.

$$N_{jst'} = E_{jst'} + R_{jst'}$$

$$N_{jct'} = E_{jct'} + R_{jct'}$$

D. INDUSTRY EMPLOYMENT - DEFINITION, SOURCES AND ESTIMATION METHODS

Definition and Sources

Industry employment in this report represents the number of jobs in an industry estimated at the place of employment rather than the place of residence. The concept of industry employment used represents the total number of jobs in an industry held not only by wage and salary workers but also by the self-employed. It can be noted that the number of unpaid family workers are also included, but that they are numerically insignificant. The employment submodel utilized in this study required annual estimates of employment for the historical period 1962-1973. These estimates for each of the 44 employment sectors presented in the employment submodel were constructed by using the following data sources:

1) Maryland Department of Employment and Social Services, Employment Security Administration. The Department has provided the Department of State Planning with detailed first quarter historical employment data by three and four digit Standard Industrial Classification (SIC) codes for each subdivision of the State. Under the Maryland Unemployment Insurance law, all firms in "covered" industries with one or more employees are counted. Workers in the following sectors are excluded from coverage: railroad; government; non-profit organizations; domestic services; and agriculture. Self-employed individuals and unpaid family workers in all sectors are also excluded from coverage.

2) U.S. Department of Commerce, Bureau of Economic Analyses. The Bureau has prepared unpublished employment estimates by 2-digit industry groups for all subdivisions for the period 1967 through 1972. In preparing these estimates, BEA has primarily utilized the ES-202 reports of the State unemployment insurance programs (State UI covered employment). Data sources utilized by BEA for the noncovered sectors include the decennial censuses, County Business Patterns data, 1969 Census of Agriculture and the 1972 Census of Governments, and private trade and business organization statistics. The BEA wage and salary employment data based on the ES-202 reports are adjusted for undercoverage, and the series includes aggregate estimates of self-employed persons. Farm and non-farm are estimated separately. Estimates of farm proprietors are constructed on the basis of information provided by the 1964 and 1969 Census of Agriculture and U.S. Department of Agriculture data. Estimates of non-farm proprietors are constructed from data provided by the Internal Revenue Service and the Social Security Administration.

Estimation Methods

In order to construct a historical industry employment series for the period 1962-1973 and to provide a basis for annual updating and to insure consistency with BEA's county personal income estimates by type of

payment, the Department of State Planning utilized the BEA employment series with appropriate adjustments. Accordingly, it was necessary to derive estimates of the number of self-employed by industry sector and to adjust our estimates for comparability with the existing 1967-1972 BEA series for the historical time period selected.

In order to derive estimates of non-farm proprietors by industry, the BEA county totals for non-farm proprietors were broken out in the same industry detail for wage and salary employment. The disaggregation was achieved through the use of a self-employed to wage and salary worker ratio by industry compiled from the 1960 and 1970 Census of Population data on class of workers available for the State of Maryland and the Baltimore and Washington, D. C. SMSA's. The ratios for intercensal years were obtained by straight-line interpolations of the two benchmark ratios. The product of these ratios and BEA estimates of wage and salary employment by industry for the period 1967-1972, yielded preliminary estimates of the self-employed by industry for each subdivision. These preliminary estimates were prorated so that their respective subdivision sum would conform to given BEA subdivision totals of non-farm proprietors. In the absence of subdivision level data on class of workers by industry comparable with the State and SMSA area information, the industry breakdown of non-farm proprietors in all non-SMSA counties was constructed by utilizing statewide ratios of the self-employed to wage and salary workers. Estimates of the self-employed by industry for Montgomery and Prince George's Counties were computed on the basis of the Washington, D. C. SMSA pattern and all component counties of the Baltimore SMSA were computed on the basis of areawide ratios.

Because the BEA employment series are presently available only for the years from 1967 to 1972, the Department estimated comparable employment for 1962, 1965, 1966, and 1973. The 1973 BEA estimates will be available to the Department in the near future and will be utilized in an updating procedure. Like BEA, the Department utilized UI industry employment data (the first quarter average) as a basic building block for industry wage and salary employment. Unlike BEA which used various sources of information for undercoverage adjustments, the Department of State Planning utilized an adjustment factor for undercoverage, i.e., BEA/UI, implicit in 1967 and 1972 BEA estimates of wage and salary employment by industry, by subdivision. The 1967 factors were applied to 1962, 1965, and 1966 UI data and the 1972 ratios to 1973 UI data were used to result in Department comparable employment series for the estimated years.

In the above estimation procedure, the Department assumed that the UI coverage or undercoverage ratios have not changed over time in each industry in each subdivision. Therefore, the resultant figures of wage and salary employment by industry in all of the estimated years were carefully reviewed in light of the State and Baltimore SMSA data by 2-digit SIC codes prepared by the Employment Security Administration (ESA). As the Department's estimates showed a high degree of comparability with ESA numbers in most of the 2-digit SIC groups, no attempt was made to prorate our subdivision estimates to the ESA data. Some discrepancies noticed in a few industries were rather consistent over time, indicating that BEA estimates in 1967-1972 themselves are not strictly comparable with ESA estimates in these years.

Our estimates of employment in industries which are not covered by the UI law were based on various sources of information and were adjusted to be comparable with BEA estimates for 1967-1972. The basic subdivision data series for railroad (SIC 40) and private households (SIC 88) came from the 1960 and 1970 Census of Population. Forestry and fisheries data were taken

from the 1962, 1965, 1966, 1967, 1972, and 1973 issues of County Business Patterns, and Federal civilian employment (SIC 91) from the U.S. Civil Service Commission's 1960, 1965, 1966, 1967, 1972, and 1973 annual reports entitled Federal Civilian Employment by Geographical area. The 1962, 1967, and 1972 Census of Governments were utilized for local government employment. For all of these uncovered industries, an annual series from 1962 to 1973 were developed by interpolation and extrapolation of available benchmark years and adjusted for comparability with the existing 1967-1972 BEA series.

Subdivision estimates of paid farm workers in 1962, 1965, 1966, and 1973 were derived by allocating State totals on the basis of subdivision distribution of cash wages paid. The wage data as reported in the 1964 Census of Agriculture were used as 1962, 1965, and 1966 allocators, and in like manner the 1969 Census of Agriculture data were used as 1973 allocators. State totals of paid farm workers were obtained from Farm Labor prepared by the U.S. Department of Agriculture, Statistical Reporting Service. Non-farm proprietors by industry in 1962, 1965, 1966, and 1973 were estimated by the same ratio method of the self-employed to wage and salary workers which was used for disaggregating given BEA subdivision totals in 1967-1972. The resultant estimates in each subdivision in 1962, 1965, and 1966 were once again modified by the 1967 factors which adjusted preliminary sets of the self-employed in 1967 obtained through the ratio method. The 1972 adjustment factors obtained were applied to 1973 preliminary estimates of non-farm proprietors to result in final sets of estimates consistent with BEA numbers in other years. This adjustment was necessary in the absence of subdivision and State data for non-farm proprietors in the estimated years. Estimates for 1962, 1965, 1966 and 1973 of farm proprietors by subdivisions were based upon the relationship between farm proprietors and paid farm workers as reflected in the BEA subdivision employment series. The 1967 relationships were applied in deriving 1962, 1965, and 1966 estimates of farm proprietors by county, and the 1972 relationships were applied for 1973 estimates.

Organization of Tables and Explanatory Notes

The following tables are a presentation of the projected population of the State of Maryland and its political subdivisions. The projections are displayed by age, race and sex-specific characteristics for each five year period from 1970 to 1990. The three components of population change, births, deaths and migration, are also included in the detailed projection tables. Additional projections for 1995 and 2000 have been included that use extrapolations of the 1970 to 1990 employment projections as a data base.

An adjustment of the 1970 population from April, 1970, to July, 1970 was made so that the employment and population projections would be compatible. The projection figures have been rounded off, and as a result, there may be a slight difference between totals and the sum of the component parts.

Organization of Tables and Explanatory Notes

The tables that follow present industry employment data estimated for the years 1965 and 1970, and projected for 1975 through 1990 in each of the major employment sectors and for each of the two digit SIC manufacturing industries in which employment exists within Maryland.

The tables are presented for the State, seven Maryland Planning regions and all subdivisions of the State which are included within each of the planning regions.

It should be noted that the employment data represents the number of jobs in each sector and that the number of persons in the armed forces are excluded from the sector data. The data is classified according to the Standard Industrial Classification (SIC). Employment above 50 has been rounded to 100, and the appearance of 0 should be taken to indicate either the absence of employment or an amount of employment below 50.

CHARLES COUNTY	132	208	94	142
DORCHESTER COUNTY	80	124	63	126
FREDERICK COUNTY	105	155	83	105
GARRETT COUNTY	110	NA	94	NA
HARFORD COUNTY	122	151	87	100
HOWARD COUNTY	121	121	74	82
KENT COUNTY	96	138	75	95
MONTGOMERY COUNTY	108	115	68	99
PRINCE GEORGE'S COUNTY	122	154	84	110
QUEEN ANNE'S COUNTY	107	140	72	94
ST. MARY'S COUNTY	163	188	126	125
SOMERSET COUNTY	96	135	61	109
TALBOT COUNTY	107	120	71	94
WASHINGTON COUNTY	96	107	84	62
WICOMICO COUNTY	94	134	68	112
WORCESTER COUNTY	93	154	73	98
BALTIMORE CITY	94	134	75	95
STATE TOTALS	108	138	77	100

THE GENERAL FERTILITY RATE UTILIZES THE TOTAL NUMBER OF BIRTHS, REGARDLESS OF THE AGE OF MOTHER, IN THE NUMERATOR AND THE FEMALE POPULATION AGES 15 TO 44 IN THE DENOMINATOR. THIS MEASURE IS THE SIMPLEST METHOD OF REMOVING THE BIASING EFFECTS OF AGE-SEX COMPOSITION AND CAN, THEREFORE, BE USED MORE EFFECTIVELY FOR COMPARISONS OF FERTILITY BOTH AMONG COUNTIES AND OVER TIME. THE 15 TO 44 AGE CATEGORY IS USED RATHER THAN AGES 15 TO 49, SINCE WOMEN IN THE 45 TO 49 AGE GROUP CONTRIBUTE RELATIVELY FEW BIRTHS TO THE TOTAL NUMBER.
